

Chapter 11 The Evolution of Populations

11.4 Hardy-Weinberg Equilibrium

I. Hardy-Weinberg Equilibrium describes populations that are not evolving-

- A. Godfrey Hardy and Wilhelm Weinberg created a mathematical model that describes the conditions under which populations would not evolve.

B. A population that is not evolving and is at Hardy-Weinberg equilibrium will have:

1. all individuals with equal reproductive success
2. mutations that do not alter the gene pool
3. no gene flow
4. a very large population
5. random mating

These conditions are hard to meet, thus most populations are evolving, although some are changing very slowly.

II. The Hardy-Weinberg equation is used to predict genotype frequencies in a population-

$$p^2 + 2pq + q^2 = 1$$

$$p + q = 1$$

- p = frequency of dominant allele
- q = frequency of recessive allele
- p² = frequency of homozygous dominant individuals
- 2pq = frequency of heterozygous dominant individuals
- q² = frequency of homozygous recessive individuals
- 1 = 100% of the population

- A. The population is NOT evolving if the calculated frequency matches the actual measured frequency.
- B. The population IS evolving if the calculated frequency differs from the actual measured frequency.

Example:
 In a population of 500 blue-footed boobies, researchers expect to find 98% of the population with webbed feet (WW, Ww), the dominant trait and only 2% with non webbed feet (ww). Grad students collect the data in the population of boobies and find:

Webbed – 480
 Non webbed – 20

1. Find the frequency of the q^2 (ww):
 $q^2 = 20 \text{ non webbed} / 500 \text{ ind in pop}$

2. Find q :
 $q = \sqrt{q^2} = \sqrt{0.04}$
3. Use $p + q = 1$ to find p :
 $p + q = 1$
 $p = 1 - q$
4. Calculate the actual genotype frequencies
 $WW \text{ (webbed)} = p^2 =$
 $Ww \text{ (webbed)} 2pq =$
 $ww \text{ (non webbed)} q^2 =$

4. Calculate the predicted genotype frequencies from what researchers hypothesized:
 98% of the population with webbed feet (WW, Ww)
 2% with non webbed feet (ww)

Find q :
 $q = \sqrt{q^2} = \sqrt{0.02}$
 =

Use $p + q = 1$ to find p :
 $p + q = 1$ therefore $p = 1 - q$
 =

Find the predicted phenotypes.
 $WW \text{ (webbed)} = p^2 =$
 $Ww \text{ (webbed)} 2pq =$
 $ww \text{ (non webbed)} q^2 = 0.02$

Do they match?

NIEM!
 0.04
 0.32
 0.04

III. There are five factors that can lead to evolution-

- A. Genetic drift – allele frequencies change in a population due to random chance
- B. Gene flow – alleles move in and out of a population when individuals migrate and reproduce with other populations
- C. Mutation – new alleles can be formed through mutation to DNA sequences leading to proteins with new functions
- D. Sexual selection – certain traits may improve mating success
- E. Natural selection – certain traits may be an advantage for survival
